ADENOVIRUS E4orf4 PROTEIN FOR INDUCING CELL DEATH

BACKGROUND OF THE INVENTION

(a) Field of the Invention

5 The invention relates to a pharmaceutical agent(s) to induce cell death in any diseases which involve inappropriate cell survival.

(b) Description of Prior Art

10 Replication of human adenoviruses in terminally differentiated epithelial cells requires an efficient mechanism to induce cellular DNA synthesis to permit replication of viral DNA and production of progeny virus. Human adenoviruses infect and kill epithelial cells very efficiently. Cell death occurs by apoptosis
15 and virus spread occurs through endocytosis by surrounding cells. Products of early region 1A (E1A) induce cell DNA synthesis and are largely responsible for cell transformation by adenoviruses. E1A produces two major mRNAs of 13S and 12S which encode proteins of
20 289 and 243 residues (289R and 243R, respectively) that are identical except for a central 46-amino acid sequence, termed conserved region 3 or CR3. Two additional regions present in the common sequence encoded by exon 1 of both E1A mRNAs are also conserved in all
25 human serotypes and have been termed CR1 and CR2 (see Fig. 1A). E1A products induce DNA synthesis through complex formation between CR2 and CR1 and the retinoblastoma tumor suppressor pRB and related p107 and p130 proteins, or between the amino terminus and CR1 and the
30 transcriptional modulator p300 and possibly related proteins (Corbeil, H.B. et al., 1994, J. Virol., 68:6697-6709). E1A-289R also activates expression of the early viral transcription units E2, E3 and E4, and certain cellular genes at least in part through inter-
35 actions with transcription factors and basal transcription machinery requiring CR3 (Teodoro, J.G., et al.,

1995, *Oncogene*, 11:467-474). In addition to CR3, transactivation of the E4 promoter has also been shown to rely to some degree on two regions encoded by the second exon of 13S mRNA, termed auxiliary regions 1 and 2, or AR1 and AR2. Production of stably transformed cells requires early region 1B (ElB) which encodes polypeptides of 19 and 55kDa that are individually capable of cooperating with ElA via separate but additive pathways (McLorie, W. et al., 1991, *J. Gen Virol.*, 72:1467-1471).

Considerable evidence indicates that a major function of ElB proteins in lytic infection and cell transformation is to suppress cytotoxic effects and apoptosis induced by expression of ElA. Without ElB, the toxicity of ElA products results in the death of ElA-transformed cells and a reduction in the yield of progeny due to the early demise of productively infected cells. ElA proteins can cause apoptosis by a process mediated by the tumor suppressor p53 (Teodoro, J.G., et al., 1995, *Oncogene*, 11:467-474), which controls growth arrest and programmed cell death pathways (Teodoro, J.G., et al., 1995, *Oncogene*, 11:467-474). Expression of ElA products results in the elevation of p53 levels. The 55kDa ElB protein binds to p53 and blocks both p53-mediated activation of gene expression and apoptosis (Teodoro, J.G., et al., 1994, *J. Virol.*, 68:776-786). The 19kDa ElB protein appears to suppress apoptosis by a mechanism that is functionally analogous to that of the cellular proto-oncogene product Bcl-2 (Nguyen, M. et al., 1994, *J. Biol. Chem.*, 269:16521-16524). Cells infected with adenovirus mutants which fail to express the 19kDa protein display enhanced cytotoxicity and extensive degradation of both cellular and viral DNA into nucleosome sized fragments (McLorie, W. et al., 1991, *J. Gen Virol.*, 72:1467-1471; Teodoro,

J.G., et al., 1995, *Oncogene*, 11:467-474). At later times, even in the presence of ElB proteins, infected cells suffer apoptotic death and viral progeny spread to neighboring cells through endocytosis of cell fragments. In addition to the induction of DNA synthesis and cell transformation, the large 289-residue (289R) ElA protein also transactivates expression of all early viral genes, including early regions 1A, 1B, 2, 3 and 4 (reviewed in Teodoro, J.G., et al., 1995, *Oncogene*, 11:467-474).

Recently our group showed that in the absence of ElB, ElA products also induce p53-independent apoptosis (Teodoro, J.G., et al., 1995, *Oncogene*, 11:467-474). Our results indicated that such apoptotic cell death was only induced by the 289R ElA protein. Furthermore, when p53-null mouse cells constitutively expressing ElA products were infected by an adenovirus vector lacking the entire ElA and ElB coding regions but containing early regions E2, E3 and E4, rapid cell death due to apoptosis was observed (Teodoro, J.G., et al., 1995, *Oncogene*, 11:467-474). We have shown that 289R induces apoptosis in p53-null mouse and human cells, and that such p53-independent cell death requires the expression of another early viral gene (Teodoro, J.G., et al., 1995, *Oncogene*, 11:467-474). Genetic analysis indicated that neither E2 nor E3 products were necessary and that one or more E4 proteins are responsible (Marcellus, S. et al., 1996, *J. Virol.*, 70:6207-6215 (1996)). E4 encodes several mostly unrelated proteins whose functions are only partially understood. These results indicated that the role of ElA-289R may be to transactivate expression of an additional early transcript whose product actually induces p53-independent apoptosis. In the present

studies we report that one or more E4 gene products appear to be responsible for such cell killing.

It would be highly desirable to be provided with a pharmaceutical agent for induction of apoptosis when such induction is useful in the treatment of human diseases which involve inappropriate cell survival.

SUMMARY OF THE INVENTION

In accordance with the present invention, a genetic approach to identify the role of individual E4 proteins in the induction of p53-independent apoptosis was used. Our results indicated that the E4orf4 protein is one of the proteins responsible. Thus E4orf4 is a powerful inducer of p53-independent cell death.

One aim of the present invention is to develop E4orf4 as a pharmaceutical agent for induction of apoptosis when such induction is useful in the treatment of human diseases which involve inappropriate cell survival.

In accordance with the present invention there is provided a pharmaceutical agent for induction of apoptosis for the treatment of human diseases which involve inappropriate cell survival, which comprises E4orf4, an analog or a biologically active fragment thereof.

In accordance with the present invention there is also provided a pharmaceutical composition for the treatment of human diseases which involve inappropriate cell survival, which comprises a therapeutic amount of E4orf4, an analog or a biologically active fragment thereof in association with a pharmaceutical carrier.

In accordance with the present invention, the expression "diseases which involve inappropriate cell survival" include, without limitation, diseases caused by HIV, herpes and/or other viral infections, Alzheimer's, cancer, arthritis, lupus among others.

The pharmaceutical agent of the present invention allows for the selective killing of cells that are prevented from dying by a virus or as a consequence of a disease state. Thus, the pharmaceutical agent of the present invention only kills the inappropriately surviving cells, such as cancer cells or viral infected cells. This results in a substantially side effect free therapy for the patient.

10 The pharmaceutical agent of the present invention includes, without limitation, any adenovirus of any serotype E4 death protein (E4-ADP) products, fragment thereof and mimetic peptides of this protein products.

Fig. 13 is a graph showing that E4orf4 when expressed by transient transfection of an E4orf4-encoding plasmid induces cytotoxicity in p53-null
10 cells, as judged by the low expression of a co-transfected reporter plasmid encoding luciferase, relative to a non-cytotoxic inducing control plasmid encoding E4orf1.

15 **DETAILED DESCRIPTION OF THE INVENTION**

In the absence of ElB, the 289- and 243-residue (289R and 243R) E1A products of human adenovirus type 5 (Ad5) induce p53-dependent apoptosis. However, our group has shown recently that the 289R E1A protein is
20 also able to induce apoptosis by a p53-independent mechanism (Teodoro et al., 1995, *Oncogene*, 11:467-474). Preliminary results suggested that p53-independent cell death required expression of one or more additional adenovirus early gene products. Here we show that both
25 the ElB-19kDa protein and cellular Bcl-2 inhibit or significantly delay p53-independent apoptosis. Neither early regions E2 or E3 appeared to be necessary for such cell death. Analysis of a series of E1A mutants indicated that mutations in the transactivation domain
30 and other regions of E1A correlated with E1A-mediated transactivation of E4 gene expression. Furthermore, p53-deficient human SAOS-2 cells infected with a mutant which expresses ElB but none of the E4 gene products remained viable for considerably longer times than
35 those infected with wt Ad5. In addition, an adenovirus vector lacking both E1 and E2 was unable to induce DNA

degradation and cell killing in E1A-expressing cell lines. These data showed that an E4 product is essential for E1A-induced p53-independent apoptosis.

5 Cells and viruses

Human Saos-2 cells (ATCC HTB 85) and 10(1) mouse embryo fibroblast-derived cells which are both deficient for p53 expression were cultured on 60mm-diameter dishes (Corning Glass Works, Corning, N.Y.) in Dulbecco's modified MEM (D-MEM) supplemented with 10% fetal calf serum (FCS) as were both NIH-3T3 and CHO cells. The cell line Saos-2/Bcl-2(3g4) which stably expresses Bcl-2 was derived for this study from Saos-2 cells by selection with G418 as was the control line Saos-2/Neo(2a2). A1.A3, A1.A6 and A1.A12 mouse embryo fibroblast cell lines expressing Ad5 E1A proteins, and Hy.A3 hygromycin-selected control lines, have been described previously (Lowe, S.W. et al., 1994, *Proc. Natl. Acad. Sci. U.S.A.*, 91:2026-2030), and were cultured in D-MEM containing 10% FCS and 100 µg/mL of hygromycin. Normally cells were infected with mutant or wild-type (wt) Ad5 at a multiplicity of 100 pfu per cell. Ad5 E1A mutants are illustrated in Fig. 1A and include deletion mutants dl1101 (residues 4-25 deleted), dl1143 (38-60), dl1107 (111-123), dl1108 (124-127), dl1143/08 (38-60 plus 124-127) and dl1132 (224-238) which have all been described previously (Marcellus, S. et al., 1996, *J. Virol.*, in press). Proteins encoded by some of the mutants used in the present studies have been presented, including the residues removed in deletion mutants. CR1, CR2, CR3, AR1 and AR2 have also been indicated. A new E1A mutant was constructed as termed AR1⁻/E1B⁻, which lacks the entire AR1 region (residues 189-200) and also fails to express E1B products. Mutant AR2⁻/E1B⁻ was generated by introducing dl1132, which lacks residues 224-238,

into a background that fails to express ElB proteins. Mutant AR1⁻/AR2⁻/ElB⁻ represents a combination of the latter two mutants. Additional ElA mutants containing single amino acid substitutions at various sites within CR3 were produced by subcloning appropriate restriction enzyme fragments from mutant ElA cDNA plasmids into genomic viral DNA, followed by rescue into virus to form mutants AD147VL (Val-147 converted to Leu), AD177CS, and AD185SG. All other mutants have been summarized in Fig. 1B. A list providing the names and defects of ElB and other mutants has been presented. Two were produced previously by our group (McLorie, W. et al., 1991, *J. Gen Virol.*, 72:1467-1471) and fail to express ElB proteins of 19kDa (originally termed pml716/2072 but now called ElB/19K) and 55kDa (originally pm2019/2250, now ElB/55K⁻). Mutant 12S/ElB⁻ (originally dl520ElB⁻) produces only the ElA-243R protein encoded by the 12S mRNA and no ElB products. Mutant ElB⁻ which expresses both major ElA products but neither the 19kDa or 55kDa ElB species was described previously (Teodoro, J.G., et al., 1995, *Oncogene*, 11:467-474), and a similar mutant that expresses only 289R in the absence of ElB, termed 13S/ElB⁻, was prepared for the present studies. A series of ElA mutants (dl1101/ElB⁻, dl1107/ElB⁻, AD147VL/ElB⁻, etc.) which express no ElB products was also produced by introducing ElA mutations into mutant ElB⁻ which expresses both 289R and 243R ElA products but no ElB (Teodoro, J.G., et al., 1995, *Oncogene*, 11:467-474). The presence of mutations in all mutants was confirmed by DNA sequencing, restriction enzyme digestion, or Southern blotting. Ad5 vectors used in this study included AdLacZ in which the El (ElA + ElB) region was replaced with the *E. coli* gene lacZ under the CMV promoter, and Ad5dl70-8 which was generated by

cotransfection of plasmids pAB7 and pBHG10 and which lacks both E1 and the entire E3 region. Adenovirus vector AdRSV μ gal.11 which lacks the entire E1 and E4 regions was a gift of Douglas Brough. In addition, some experiments were carried out with human adenovirus type 2 (Ad2) mutant d.1019 which contains deletions that eliminate expression of all E4 products and which was propagated on W162 monkey cells, as described previously (Bridge, E. et al., 1989, *J. Virol.*, 63:631-638). Other E4 mutants (Bridge, E. et al., 1989, *J. Virol.*, 63:631-638) have been summarized in Fig. 10.

DNA fragmentation

Low molecular weight DNA was isolated from mock- or Ad5-infected cells as described in Teodoro et al. (1995, *Oncogene*, 11:467-474). For such experiments, 60mm-diameter plates of cells were harvested at 40 h post-infection and lysed in pronase lysis buffer comprised of 10mM Tris-HCl (pH 8) containing 5mM EDTA, 100mM NaCl, and 1 mg/mL (w/v) pronase to which SDS was added to 0.5% (w/v). Cell lysates were incubated at 37°C for 2 h and NaCl was added to a final concentration of 1M. Samples were then incubated overnight at 4°C and centrifuged at 15,000 x g for 30 min. Extracted nucleic acids were treated with RNAase A and analyzed on 1% agarose gels stained with ethidium bromide.

Cell viability assays

Cells were infected with wt or mutant virus in 24-well plates containing cells at about 80% confluence. At various times following infection adherent and non-adherent cells were pooled and viability was assessed by Trypan Blue™ exclusion. At least 300 cells were counted at each time point.

Measurement of E1A-mediated transactivation of the adenovirus E4 promoter

Transactivation assays were performed using NIH 3T3 or CHO cells plated at a density of 2×10^5 cells on 60 mm-diameter dishes. The E4 reporter plasmid was E4-CAT containing the E4 promoter upstream of the chloramphenicol acetyltransferase (CAT) gene. Transient co-transfections were performed by the calcium phosphate precipitation method using 2.5 μ g of reporter plasmid DNA and 2.5 μ g of DNA from plasmids expressing wt or mutant E1A products as described in Marcellus et al., 1996. Cells were glycerol shocked after 12h and then harvested 36 h later. CAT assays were performed using cell extracts containing equal amounts of β -galactosidase activity. The amount of activity was quantified from TLC plates using a Fujix Bas 2000™ Phosphorimager.

E1A-induced p53-independent apoptosis is inhibited by both the E1B-19kDa protein and cellular Bcl-2

Previous studies indicated that whereas both major Ad5 E1A products could induce apoptosis in cells expressing p53, only the 289R E1A protein could do so in cells lacking p53 (Teodoro, J.G., et al., 1995, *Oncogene*, 11:467-474). Fig. 2 shows the pattern of DNA fragmentation in p53⁻ mouse 10(1) cells infected by various Ad5 mutants. 10(1) cells which fail to express p53 were infected with various Ad5 mutants, or they were mock-infected, and at 40 h p.i., low molecular weight DNA was analyzed by agarose gel electrophoresis. The contents of individual lanes are as indicated in Fig. 2. Extracts from mock-infected cells (lane 1) and those infected with wt Ad5 (lane 2) which expresses E1B products displayed reduced levels of extracted low molecular weight DNA and little or no degraded DNA, as did those from cells infected with mutant E1B/55K⁻ (lane 4) which produces the E1B-19kDa protein but not

the ElB-55kDa product. With cells infected with mutant ElB⁻ which synthesizes both the 289R and 243R ElA proteins but which produces no ElB products (lane 6), large amounts of DNA were extracted and high levels of nucleosome-sized DNA fragments were evident. Similar results were also obtained with cells infected with ElB/19K⁻ (lane 5) which produces the ElB-55kDa species but not the 19kDa protein. Induction of DNA degradation in these p53⁻ cells did not occur following infection with 12S/ElB⁻ (lane 3) which produces only ElA-243R and no ElB, but it did occur with 13S/ElB⁻ (lane 7) which yields only ElA-289R in the absence of ElB products. Thus as shown previously, ElA-289R but not 243R induces p53-independent apoptosis in the absence of ElB proteins. In addition the results indicated that the ElB 19kDa polypeptide but not the 55kDa ElB product is able to protect against apoptosis induced by ElA in the absence of p53.

To examine the specificity of inhibition of apoptosis further, studies were conducted to determine if the cellular Bcl-2 protein is also able to prevent p53-independent apoptosis as several previous studies had shown that Bcl-2 and the ElB-19kDa protein may be functionally similar (Nguyen, M. et al., 1994, *J. Biol. Chem.*, 269:16521-16524). Human Saos-2 cells which are defective for synthesis of p53 were transfected with cDNAs encoding the human Bcl-2 protein and the neomycin resistance marker and several cell lines were selected using G418. One such Bcl-2 expressing clone, termed Saos-2/Bcl-2(3g4), and a control SAOS-2 clone, SAOS-2/neo(2a2) selected only for resistance to G418, were infected with wt Ad5, mutants 12S/ElB⁻ or ElB/19K⁻, or were mock-infected, and cell viability assays were conducted at various times after infection. In Fig. 3, p53-deficient human Saos-2/neo(2a2) cells (panel A) or

Saos-2/Bcl-2(3g4) which express human Bcl-2 constitutively (panel B) were mock-infected or infected with wt, ElB/19K⁻ or 12S/ElB⁻ and were tested for viability by a Trypan Blue™ exclusion assay at various times following infection, as described above. Results have been presented as the logarithm of the % viable cells, and symbols are as indicated in Fig. 3. Fig. 3A shows that SAOS-2/neo(2a2) control cells were killed by the ElB/19K⁻ virus that expresses ElA-289R, but those infected with wt or 12S/ElB⁻ remained almost as viable as mock-infected cells during the test period. Fig. 3B shows that with Saos-2/Bcl-2(3g4) cells which stably express high levels of Bcl-2, little cell death was induced by the ElB/19K⁻ virus. Similar results were obtained with three other control and Bcl-2 producing SAOS-2 cell lines. Thus like the ElB-19kDa protein, Bcl-2 also blocks ElA-induced p53-independent apoptosis.

20 **Role of ElA domains in p53-independent apoptosis.**

To investigate the regions of ElA products involved in causing p53-independent cell death, p53⁻ mouse 10(1) cells were infected with Ad5 mutants which fail to express ElB and which harbor a variety of defects at various regions of the ElA molecule. Extracts were harvested and analyzed on gels to determine the extent of degradation of low molecular weight DNA. In Fig. 4, an experiment in p53-deficient 10(1) cells similar to that described in Fig. 2 was performed using a series of Ad5 ElA mutants defective in expression of ElB products. The contents of individual lanes are as indicated in Fig. 4. Fig. 4 shows that again mutant ElB/19K⁻ (lane 3) induced DNA degradation whereas such did not occur with wt Ad5 (lane 2) or mock-infected cells (lane 1). Mutants which affected the ElA transactivation function associated with CR3

all failed to induce DNA degradation. These included 12S/E1B⁻ (lane 8), and point mutants AD147VL/E1B⁻, AD171CS/E1B⁻ and AD185SG/E1B⁻ (lanes 9 to 11, respectively) which carry single residue substitutions at critical residues in CR3 that eliminate E1A transactivation activity. In addition, deletion of AR1 or both AR1 and AR2 (AR1⁻/E1B⁻ and AR1⁻/AR2⁻/E1B⁻ in lanes 12 and 14) also eliminated DNA degradation whereas removal of AR2 alone (AR2⁻/E1B⁻ in lane 13) had little effect. Interestingly, mutants in CR2 which eliminate complex formation with pRB and related proteins (dl1107/E1B⁻ and dl1108/E1B⁻ in lanes 5 and 6) had no effect on the induction of DNA degradation, whereas those that eliminated binding of p300 by removal of the N-terminus (dl1101/E1B⁻ in lane 4) or a portion of CR1 as well as the pRB binding site (dl1143/08/E1B⁻ in lane 7) no longer caused this effect. These results suggested that E1A-induced p53-independent apoptosis required the CR3 transactivation domain, AR1, and the regions necessary for binding of p300 but not pR3-related proteins. Fig. 5 shows that similar results were obtained with these mutants in cell killing assays. An experiment similar to that described in Fig. 3 was carried out in SAOS-2 cells infected with various E1A mutants defective in expression of E1B products. Results have been presented as the logarithm of the % viable cells, and symbols are as indicated in Fig. 5. Cell death was induced by the E1B/19K⁻ virus which expresses both E1A products and by dl1107/E1B⁻. Mutant AR2⁻/E1B⁻ which lacks AR2 also killed, but was consistently less toxic than the former viruses. All other mutants affecting CR3, AR1 and the p300 binding sites failed to kill significantly during the test period.

Activation of E4 expression and apoptosis.

The requirement for AR1 suggested that E4 products might somehow be involved in the induction of p53-independent apoptosis as this region is not important in the activation of other early viral transcription units. Studies were therefore carried out to examine the pattern of E1A transactivation of the E4 promoter in which plasmid DNA encoding various mutants forms of E1A-289R was co-transfected into NIH-3T3 or CHO cells along with DNA from E4-CAT, a construct that encodes CAT under the control of the Ad5 E4 promoter. Table 1 shows that in addition to CR3, activation of the E4 promoter required AR1 and to some extent AR2.

Table 1
E4 Transactivation by E1A Mutants

E1A Mutant	Mutation	Region Affected	E4 CAT * Activity (% wt \pm S.D.)
wt	none	none	100
d11101	Δ 4-25	N-terminus	30 \pm 11

* CHO or 3T3 cells were transfected with plasmid DNA encoding various E1A mutants and CAT under the Ad5 E4 promoter.

Cell extracts were assayed for CAT activity as described above. The activity has been expressed as a % of that obtained with wt. Three independent assays were done for each mutant.

In addition, regions at the N-terminus and in CR1 involved in binding of p300 also were of some im-

portance. These results closely paralleled the pattern of E1A-induced p53-independent apoptosis and suggested that E4 products might be involved.

5 **E2 and E3 products are not required for apoptosis**

It was unlikely that E2 products were responsible for the induction of p53-independent apoptosis for two reasons. First, in addition to CR3, complex formation involving CR2 and the pRB family of proteins activates E2 expression, and CR2 was shown to be of little
10 importance in cell killing. Second, reasonably high levels of expression of E2 proteins are known to be induced by the E1A-243R protein which is completely unable to induce p53-independent apoptosis. Thus
15 experiments were carried out to determine if any E3 products were involved. The A1.A3 mouse embryo fibroblast cell line lacking p53 but expressing Ad5 E1A proteins, and Hy.A3 hygromycin-selected p53⁻ control cells (Lowe, S.W. et al., 1994, *Proc. Natl. Acad. Sci. U.S.A.*, 91:2026-2030), were infected with wt Ad5, the
20 E1B/19K⁻ virus, adenovirus vector AdLacZ which contains lacZ in place of E1A and E1B, or with vector Ad5dl70-8 which lacks both the entire E1 and E3 regions. Cell extracts were assayed for the presence of degraded DNA as before. Fig. 6 shows that high levels of DNA degradation were induced in A1.A3 cells with the 19K⁻ mutants as well as both adenovirus vectors. Cell lines
25 expressing 289R and 243R E1A proteins constitutively, or the Hy.A3 non-expressing control cell line, were mock-infected or infected with wt Ad5 or adenovirus vectors AdLacZ or Ad5dl70-8. After 40 h, DNA was extracted and analyzed by agarose gel electrophoresis. The contents of individual lanes are as indicated in Fig. 6. Similar results were also obtained with two
30 other similar E1A-expressing cell lines, A1.A6 and A1.A12. Fig. 6 also shows that in the control cells

lacking constitutive E1A expression, only the E1B/19K⁻ virus induced DNA degradation. These results indicated that E3 products were not required for induction of p53-independent apoptosis by E1A under these conditions.

E4 proteins are essential for p53-independent apoptosis

To determine directly if E4 products are involved in the induction of cell death, as suggested by experiments described above, two approaches were taken. In the first, human p53⁻ SAOS-2 cells were infected with wt Ad5 or Ad2, or with Ad2 mutant dl1019 which produces no E4 proteins (Bridge, E. et al., 1989, *J. Virol.*, 63:631-638), or they were mock-infected. Although such viruses express E1B proteins and thus are protected from E1A-induced apoptosis, it was thought that if E4 products were essential for p53-independent cell death, some difference in long term cell survival might be observed, and thus at various times up to 10 days, infected cultures were tested for cell viability. Fig. 7 shows that cells infected either by wt Ad5 or Ad2 virus began to die at about 100h p.i., and by 240h p.i. almost all of the cells were dead. SAOS-2 cells were mock-infected or infected with wt Ad5 or Ad2, or dl1019 which expresses no E4 products. At various times up to 10 days cell viability was assessed by Trypan Blue™ exclusion. Data have been expressed as % cell viability and symbols are as indicated in the Fig. 7. Such was not the case with dl1019-infected cells which remained almost as viable as mock-infected cells even 10 days after infection. These results indicated that an E4 product was involved in cell killing in the absence of p53. This idea was confirmed in experiments involving infection of E1A-expressing p53⁻ A1.A3 cells with the adenovirus vector AdRSVβgal.11 in which both the E1 and E4 regions had been completely

deleted. Fig. 8 shows that in control Hy.A3 p53⁻ cells which do not express E1A, only the E1B/19K⁻ Ad5 mutant caused DNA degradation, and neither wt, 12S/E1B⁻, nor the AdRSV β gal.11 vector had any significant effect.

- 5 Cell lines expressing 289R and 243R E1A proteins constitutively, or the Hy.A3 non-expresser control cell line, were mock-infected or infected with wt Ad5, E1B/19K⁻, 12S/E1B⁻, or the adenovirus vector AdRSV β gal.11 which lacks both E1 and E4. After 40 h,
- 10 DNA was extracted and analyzed by agarose gel electrophoresis. The contents of individual lanes are as indicated in the Fig. 8. With A1.A3 cells, both the E1B/19K⁻ and 12S/E1B⁻ induced DNA degradation, but the AdRSV β gal.11 vector still had little effect. Similar
- 15 results were obtained with the other two sister cell lines, A1.A6 and A1.A12 discussed above. The ability of this virus to induce apoptosis in A1.A3 cells was analyzed further in cell killing experiments. Cell lines expressing 289R and 243R E1A proteins constitutively (panel A), or the Hy.A3 non-expresser control cell line (panel B), were mock-infected or infected
- 20 with wt Ad5, E1B/19K⁻, 12S/E1B⁻, or the adenovirus vector AdRSV β gal.11. At various times after cell viability was assessed by Trypan BlueTM exclusion. Data have been expressed as % cell viability and symbols are as indicated in the Fig. 9. Fig. 9A shows that in the Hy.A3 control cells, only the E1B/19K⁻ virus induced cell death, whereas in A1.A3 cells both the E1B/19K⁻ and 12S/E1B⁻ viruses did so. However in both cases the
- 25 AdRSV β gal.11-infected cells remained as fully viable as mock-infected cultures. These data thus confirmed that an E4 product is responsible for E1A-induced p53-independent cell death.
- 30

RESULTS AND DISCUSSION

To identify which E4 product is responsible for induction of E1A-dependent p53-independent apoptosis, p53-null mouse 10(1) cells were infected with wt Ad5 or with mutants carrying deletions in various portions of the E4 region (see Fig. 10). Fig. 11 shows that as shown above, cells in cultures infected by the wt virus began to die by about 125 hours following infection, and death was almost complete by 240 hours. Little cell death was observed in mock-infected cultures or in those infected by mutant dl1019 which lacks the entire E4 region. Cell death similar to that found with wt was observed with E4 mutants dl1013 which expresses E4orf6 and E4orf4, whereas little death occurred with mutant dl1010 which expresses all E4 products except E4orf6. These results indicated that cell death occurred only when the E4orf6 protein was expressed and did not take place during the course of the experiment in its absence. Thus it is clear that expression of the E4orf6 protein may be important for the p53-independent apoptosis induced by the 289R E1A product.

Further experiments using mutants dl1014 which expresses E4orf4 only, dl1015 which expresses E4orf4 and E4orf3, dl1011 which expresses no E4 products, as well as much infected cells, are illustrated in Fig. 12. These results indicate that expression of E4orf4 alone induced cell death. Thus, E4orf4 is capable of inducing p53-independent cell death.

This conclusion was confirmed in a second type of experiment in which E4orf4 was expressed alone in the absence of other viral proteins using transient transfection with E4orf4 plasmid DNA in combination with a reporter plasmid encoding luciferase (Fig. 13). In this experiment E4orf4 alone was shown to have

potent cytotoxic activity as judged by the substantial reduction in luciferase activity.

It has been known for some time that adenovirus E1A products induce DNA degradation, rapid cell death and other hallmarks of apoptosis when expressed in the absence of E1B products whose major role in lytic infection and transformation is to suppress E1A toxicity. Both the 289R and 243R E1A proteins are able to induce apoptosis through p53-dependent pathways.

E1A proteins also induce apoptosis in cells lacking p53 (Teodoro, J.G., et al., 1995, *Oncogene*, 11:467-474). We found that this p53-independent apoptosis was elicited only by the 289R E1A protein, and preliminary evidence suggested that expression of one or more additional early viral genes regulated by E1A-289R was required. The present experiments indicated that the E1B-55kDa protein is unable to block this effect, but both the E1B-19kDa product and the cellular suppressor of apoptosis Bcl-2 significantly inhibited this response.

The major goal of this work was to identify which early viral transcription units were required to induce cell death in the absence of p53. Results obtained with E1A mutants clearly indicated the CR3 is important. Furthermore, CR3-mediated transactivation activity appeared to be required, as several point mutants in CR3 which were known to eliminate transactivation of target genes were defective for induction of DNA degradation and cell killing. Of great interest were results obtained with mutants with defects outside CR3. Mutant dl1108 which lacks the core binding site for pRB and related proteins induced p53-independent apoptosis like wt. However, mutant dl1101 which binds pRB at reasonably normal levels but fails to bind the p300 transcriptional modulator was totally defective. These

results may suggest that interactions between p300 and 289R are essential to institute cell death pathways. Another possibility was offered by results obtained with two additional mutants with defects in the AR1 and
5 AR2 regions encoded by the second exon of the 13S E1A mRNA. The AR1-defective mutant was unable to induce p53-independent apoptosis, and that lacking AR2 was somewhat impaired. These results corresponded exactly to the relative abilities of these mutant E1A molecules
10 to transactivate the E4 promoter. We also found that dl1101 was partially defective for transactivation of E4, thus suggesting both that E4 products might be involved in induction of cell death and that interactions of 289R with p300 may reflect more a requirement
15 for transactivation of E4 transcription than a direct role in apoptosis. This question will only be answered by further experiments using a new series of mutants.

Early regions E2, E3 and E4 encode a variety of products which could play some role in cell death. E2
20 proteins are largely involved in viral DNA synthesis. However, it is unlikely that any play an essential role in cell death. First, E2 transcription requires not only CR3, but also the formation of complexes with pRB which result in the activation of the E2F family of
25 transcription factors and E2 gene expression. Our results clearly indicated that complex formation with pRB was not essential for apoptosis. Second, the adenovirus vector AdRSV β gal.11 contains a wt E2 region and yet was defective for induction of p53-dependent
30 apoptosis in E1A-expressing cells. The E3 region encodes several proteins which affect virus-host interactions, however, the adenovirus vector Ad5dl70-8 was fully capable of inducing apoptosis in E1A expressing p53-deficient cells. As discussed above, the pattern of
35 apoptosis observed with E1A mutants suggested that the

early viral proteins associated with cell death are encoded by E4. Direct evidence that an E4 protein is responsible was obtained from experiments in which the pattern of death was observed in p53-null SAOS-2 cells infected by wt Ad5 or a mutant defective in E4 expression. Because ElB products were expressed by these viruses, cell death occurred only at late times, but the observation that E4 mutant-infected cells displayed considerably retarded death clearly implicated an E4 product in the death process. Final confirmation came from results with the AdRSV β gal.11 adenovirus vector which was defective for cell killing. This virus was unable to induce DNA degradation or cell killing in p53-deficient cells expressing ElA.

It is likely that the E4orf4, or the adenovirus E4orf4 Death Protein (E4orf4-ADP), is capable of killing human cells following productive infection by adenoviruses. Cell death could be induced early after infection following expression of ElA proteins, however, p53-dependent apoptosis, which is induced directly by ElA, is blocked by expression of both the 55kDa and 19kDa ElB proteins. Following expression of the E4orf4-ADP, infected cells could die by p53-independent apoptosis were it not for the ElB-19kDa product which blocks cell death until late in infection (Marcellus, S. et al., 1996, *J. Virol.*, 70:6207-6215 (1996)). Cell death may eventually occur because the levels of the E4orf4-ADP become too elevated for suppression by ElB-19K.

The E4orf4-ADP could be of use in killing cells that accumulate in several disease states, including some auto-immune disorders and cancer. Such cells fail to die by apoptosis and, at least in many cancers, one reason is because many cancer cells lack or express a mutant form of p53. These cells would, however, be

susceptible to killing by the E4orf4-ADP. Further studies will be necessary to define the specificity of cell killing and the mechanism of induction of apoptosis by the E4orf4-ADP.

- 5 While the invention has been described in connection with specific embodiments thereof, it will be understood that it is capable of further modifications and this application is intended to cover any variations, uses, or adaptations of the invention following,
- 10 in general, the principles of the invention and including such departures from the present disclosure as come within known or customary practice within the art to which the invention pertains and as may be applied to the essential features hereinbefore set
- 15 forth, and as follows in the scope of the appended claims.

I CLAIM:

1. A pharmaceutical agent for induction of apoptosis for the treatment of human diseases which involve inappropriate cell survival, which comprises E4orf4, an analog or a biologically active fragment thereof.
2. A pharmaceutical composition for the treatment of human diseases which involve inappropriate cell survival, which comprises a therapeutic amount of E4orf4, an analog or a biologically active fragment thereof in association with a pharmaceutical carrier.
3. A pharmaceutical composition for the treatment of human diseases which involve inappropriate cell survival, which comprises a therapeutic amount of a compound which induces protein phosphatase 2a in association with a pharmaceutical carrier.
4. The composition of claim 3, wherein said compound is an agonist of E4orf4 or a compound which mimic E4orf4 activity.
5. A pharmaceutical composition for the treatment of human diseases which involve inappropriate cell survival, which comprises a therapeutic amount of a compound which induces apoptosis or other cytotoxic effects analogous to E4orf4 biological activity in association with a pharmaceutical carrier.

ABSTRACT OF THE INVENTION

The present invention relates to a pharmaceutical agent for induction of apoptosis for the treatment of human diseases which involve inappropriate cell survival, which comprises E4orf4, an analog or a biologically active fragment thereof. There is also provided a pharmaceutical composition for the treatment of human diseases which involve inappropriate cell survival, which comprises a therapeutic amount of E4orf4, an analog or a biologically active fragment thereof in association with a pharmaceutical carrier.
